Sternal wound infection (SWI) is a serious complication after cardiac surgery. Delayed sternal closure (DSC) is associated with a significantly higher infection rate. Despite this, many surgeons perform DSC to reduce postoperative pain and risk of dehiscence. To describe the incidence, characteristics and outcomes of SWI associated with DSC, we retrospectively analysed 85 consecutive cardiac surgery patients who underwent DSC over a 12-year period. The median postoperative day of closure was 5 (range, 3-15). SWI occurred in 14 patients (16.5%) and was associated with a higher incidence of complex coronary artery disease (P = 0.01), a prolonged cardiopulmonary bypass time (P = 0.007) and a longer intensive care unit stay (P and be able to charge your iPhone right from the charging station itself.
